Density of methanolic electrolyte solutions at  $T = 298$  K and  $P = 1$  bar:

# Osmotic pressure for activity of solvents

In a dense liquid, it is hard to compute the chemical potential (or activity) by inserting test particles.

**OPAS method:** Compute the osmotic pressure from the force acting on a virtual semipermeable membrane.

External harmonic potential constraining the solute inside.

No external potential for the solvent.

$$\Pi = P^{\text{in}} - P^{\text{out}}$$

# Osmotic pressure for activity of solvents

**Step 1:** Pseudo-*NPT* run, where the barostat is adjusted to regulate  $P^{\text{out}}$ .  
**Step 2:** *NVT* simulation.

**OPAS method:** Compute the osmotic pressure from the force acting on a virtual semipermeable membrane.

Solvent activity (Raoult normalization) from osmotic pressure:

$$T \ln a_{\text{solv}}^{\text{in}} = - \int_{P^{\text{out}}}^{P^{\text{in}}} dP v_{\text{solv}}^{\text{pure}} \approx - \Pi v_{\text{solv}}^{\text{pure}}$$

Density and compressibility of the pure solvent are easy to compute.

# Validation of the OPAS method

Test case: Mixture of argon (LJ) and oxygen (2CLJQ).

Ar is treated as solvent and moves freely through the simulation volume.  
The solute  $O_2$  is confined by the membranes to the inner compartment.

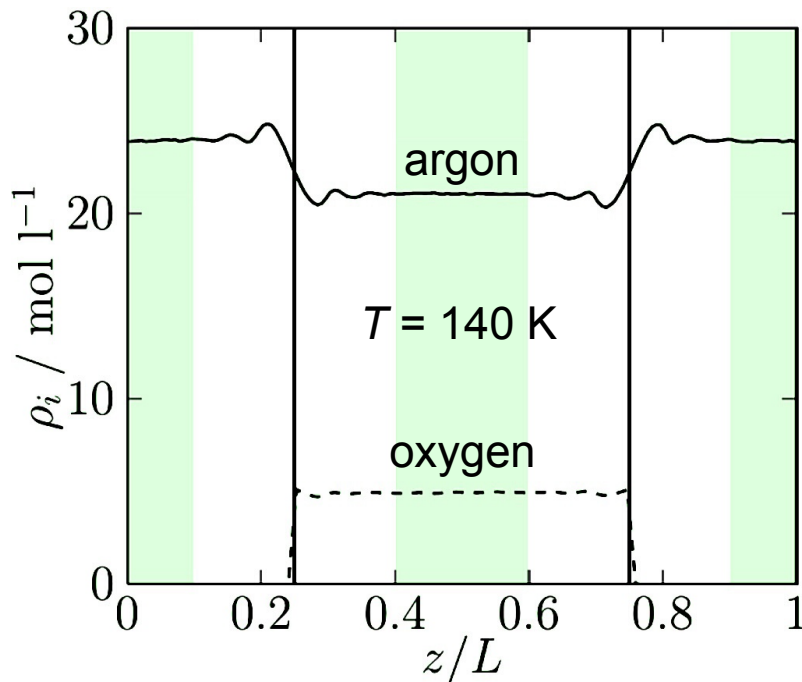

# Validation of the OPAS method

Test case: Mixture of argon (LJ) and oxygen (2CLJQ).

Osmostic pressure from force acting on the membranes:  $6.33 \pm 0.06$  MPa.

Osmostic pressure from difference between compartments:  $6.1 \pm 0.2$  MPa.

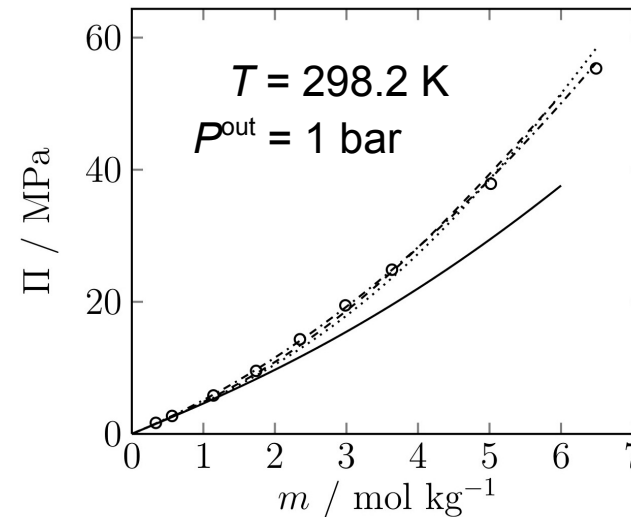

# Water activity in electrolyte solutions

Validation of OPAS simulation results against literature data for aqueous NaCl solution using

- the SPC/E water model,
- the Joung-Cheatham NaCl model.

Validation against:

———— Correlation to experimental data by Hamer and Wu

# Salt activity in aqueous solution

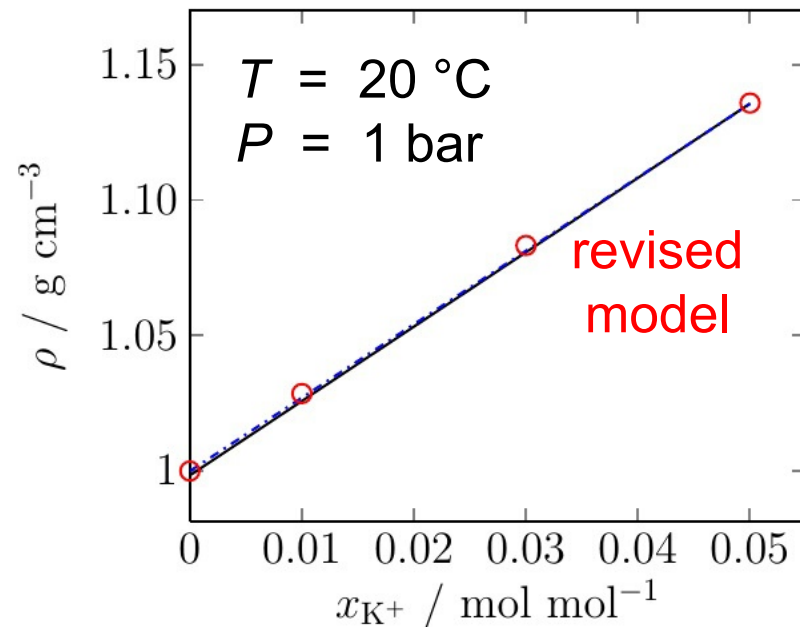

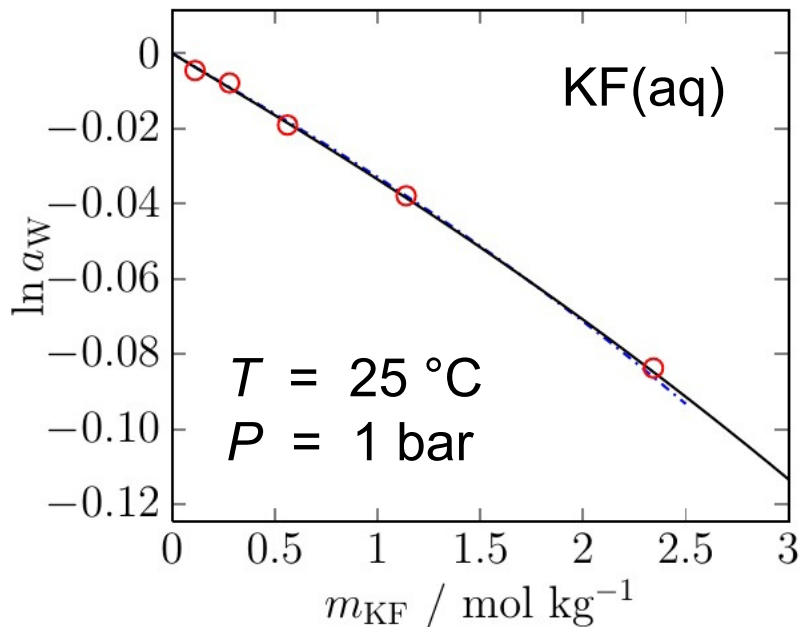

# Reparameterization to solvent activity

New  $\sigma(\text{K}^+) = 2.06 \text{ \AA}$  (old:  $2.77 \text{ \AA}$ ),  $\sigma(\text{F}^-) = 3.94 \text{ \AA}$  (old:  $3.66 \text{ \AA}$ ).

For a specific combination of ions, the accuracy for the chemical potential can be improved without a loss in accuracy for the density.

# Conclusion

In previous work of our group, LJ + point charge models of the alkali and halide ions were developed. The  $\sigma$  parameters were collectively parameterized to the reduced **density of aqueous salt solutions**.

The models were validated against **new experimental data** for non-aqueous solutions, and for aqueous solutions at a different temperature.

By **OPAS simulation** with virtual semipermeable membranes, the influence of salts on the chemical potential or **activity of water** can be determined at a higher precision than e.g. by test particle insertion.

The **activity of the solute** can be obtained by Gibbs-Duhem integration.

In many cases, the models from previous work agree well with experimental activity data. In other cases, the agreement can still be improved.
