Lines: General correlation  $\theta(T^*, W^*, \rho)$  for contact angles of LJ systems.

# Fluid-solid interaction and boundary slip

Scenario: Fluid and solid LJTS  
with  $\epsilon_w = 100 \epsilon_f$  and  $\sigma_w = \sigma_f$

$$T_w = 0.8 \epsilon_f$$

$$\Delta y_w = 15 \sigma_f$$

$$\Delta v_w = 0.5 (\epsilon_f / m_f)^{1/2}$$

Fluids **attracted more strongly** to the walls support greater shear rates **without boundary slip**. A stronger unlike interaction between the fluid and the wall **improves heat transfer** from the fluid to the wall.

# Nanoindentation and nanoscratching

Fluid and fluid-solid: LJTS  
 Fluid-solid:  $\zeta = 0.5$   
 Iron: Mendeleev potential<sup>1</sup>  
 Indenter: Rigid cylinder  
 (with LJTS sites)

Thermostat acting on remote part of the work piece,

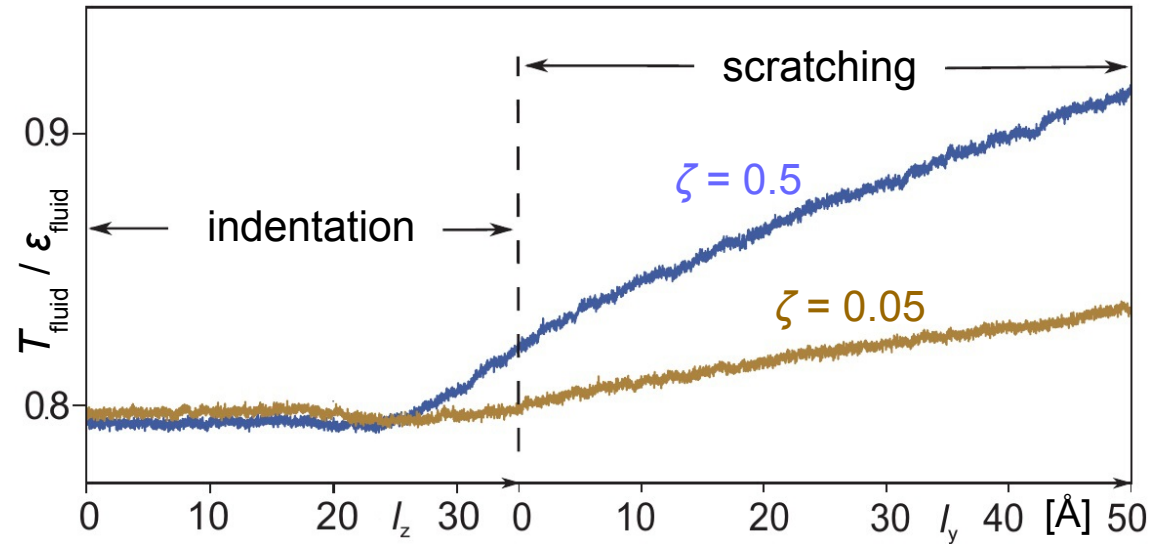

$$T_{\text{ext}} = 0.8 \varepsilon_f,$$

fluid density  $\rho_f = 0.8 \sigma^{-3}$ .

# From planar to structured surfaces

Investigation of the contact angle for a variety of surface morphologies:

The dependence  $\theta_0(T, W, \rho_s)$  is known.<sup>1</sup>

<sup>1</sup>S. Becker *et al.*, *Langmuir* 30, 13606, 2014

# Cassie and Wenzel models

Surface structure is reduced to characteristic ratios of surface areas:<sup>1,2</sup>

$f_1$  = unstructured area (“top”)

$f_2$  = structured area (“bottom”)

$f_3$  = excess surface area (“side”)

Wenzel roughness factor  $w = \frac{f_1 + f_2 + f_3}{f_1 + f_2}$

unstructured fraction  $\phi = \frac{f_1}{f_1 + f_2}$

The quantities  $w$  and  $\phi$  describe **average** surface properties.

<sup>1</sup>R. N. Wenzel, *Ind. Eng. Chem.* 28, 988, **1936**, <sup>2</sup>A. Cassie, S. Baxter, *Transact. Faraday Soc.* 40, 546, **1944**

# Cassie model and impregnation

# Contact angle on an impregnated surface

$$H = 4.7 \sigma_f$$

$$B = 6 \sigma_f$$

Wenzel roughness factor:  $w = 1.78$

Unstructured fraction:  $\varphi = 0.5$

Young contact angle:  $\theta_0 = 55^\circ$

Wenzel model:  $\theta = 0^\circ$

Cassie model:  $\theta = 38^\circ$

# Contact angle on an impregnated surface

Young contact angle:  $\theta_0 = 55^\circ$

Wenzel model:  $\theta = 0^\circ$

Cassie model:  $\theta = 38^\circ$

Wenzel roughness factor:  $w = 1.78, 3.35$

Unstructured fraction:  $\varphi = 0.5$

# Heterogeneously structured surfaces

Contact angles on the impregnated *homogeneously structured* surfaces:

$$\theta = 45^\circ \text{ for } B = 6 \sigma_f \text{ and } \theta = 58^\circ \text{ for } B = 2 \sigma_f.$$

# Asymmetrical droplet contours

A symmetry break can be imposed by the boundary conditions, even if the structures themselves have a strictly cylindrical outline.

$\beta$ -cristobalite

$T = 298 \text{ K}$

# Surface morphology and dynamic wetting

**Contact line pinning** due to the structure of the three-phase contact region causes the deviation between advancing and receding contact angles.

D. Bonn *et al.*, *Rev. Mod. Phys.* 81, 739, 2009

F. Schellenberger *et al.*, *Phys. Rev. Lett.* 116, 096101, 2016

Physical and chemical inhomogeneities are decisive for dynamic wetting.

# Contact line pinning at an edge

Epitaxial Cassie state

Line pinning does not occur exactly at the edge. The contact line is shifted inward due to the presence of a precursor layer.

# Dynamic wetting: Spontaneous transition

Gibbs inequality:

$$\theta_0 \leq \theta \leq \theta_0 + \alpha$$

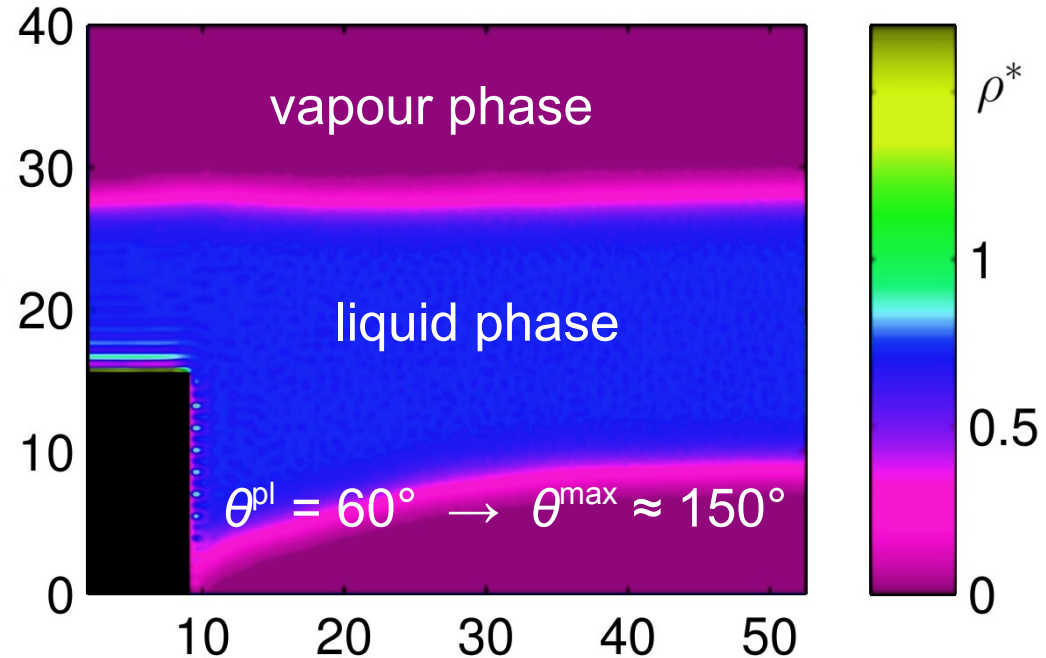

# Dynamic wetting: Spontaneous transition

Case with  $\theta^{\max} = 180^\circ$

Case with  $\theta^{\max} < 180^\circ$

Present simulation results are in agreement with the Gibbs inequality.

# Dynamic wetting: Activated transition

Contact line motion from one groove to the next is an activated process.

# Dynamic wetting: Activated transition

Preferred mechanism at a nanostructured surface:

1. Expansion of the droplet in **radial direction** by nucleation of a bridge between two impregnated areas<sup>1</sup>
2. Complete or partial filling of the next groove by expansion of the droplet in **axial direction**

The present MD simulations confirm that dynamic wetting on nanostructured surfaces follows the mechanism proposed by de Gennes.<sup>1</sup>

<sup>1</sup>P. G. de Gennes, *Rev. Mod. Phys.* 57, 827, 1985.

# Scale bridging by mesoscopic approaches

Relaxation simulations based on a square-gradient **phase field model**:<sup>1</sup>

Allen-Cahn

$$\dot{\phi} = -M \nabla_{\phi} A$$

Future aims:

- Include inertia, external driving forces, non-equilibrium steady states
- Consider fluctuations, e.g. on the basis of fluctuating hydrodynamics

<sup>1</sup>F. Diewald, C. Kuhn, R. Blauwhoff, M. Heier, S. Becker, S. Werth, M. Horsch, H. Hasse, and R. Müller, *Proc. Appl. Math. Mech.* 16, 519, **2016**.

# Conclusion

Scalable molecular simulation permits the crossover from the nanoscale to the microscale for large heterogeneous systems, while for thermodynamic properties of homogeneous systems, fast response times can be reached.

For the LJTS model, the dependence of the Young (planar) contact angle on the fluid-solid interaction, temperature, and solid density was determined. The results apply to many systems with dispersive interactions.

At a nanostructured surface, the deviation between the observed contact angle and the Young contact angle is (qualitatively) incorrectly described by Cassie and Wenzel model predictions.

Spontaneous and activated modes of dynamic wetting were considered by MD simulation. Nucleation of a bridge, as proposed by de Gennes, becomes the dominant mechanism when the structures are small.
